# // MODU (MAY-SEPT 2026)

link to the website >> http://linklinklink383838

**# role:**

UX designer, cognitive accessibility & neurodivergent UX researcher, gamification design, personalisation systems, interface designer, accessibility checker (WCAG), frontend developer, graphic design assistant, usability tester

**# tools:**

Figma, GitHub, Adobe Photoshop & Illustrator, React Native, Expo (SDK 54), TypeScript, Supabase, react-native-filament, Blender

## / MODU is...

a gamified companion app that turns a chaotic paper manual into one step, one part, one calm decision at a time virtual furniture 3D assembly — personalised in real time to how your mind processes a build, not a generic average of everyone's. Today it guides builds of pieces modelled on IKEA furniture, and the same approach works for any furniture brand, so the team is now looking for furniture businesses to partner with.

**Why gamified?** Long, fiddly builds are easy to abandon half-finished, and research links early, frequent rewards to staying engaged. So every finished build in MODU earns XP (experience) and coins, then moves into a 3D isometric room user arranges in their own way. Users can add friends, visit their rooms and leave impressions, so a finished build is something one can show, not just keep.

## < PHASE 01: IDENTIFYING THE PROBLEM >

**the users are**

people with cognitive struggles associated with ADHD, Autism (ASD/AuDHD), Dyslexia and Dyspraxia — plus first-time assemblers of any kind, who hit the same walls without a diagnosis behind them

**they encounter**

overwhelming manuals that assume perfect working memory, perfect spatial rotation and zero sensory friction: unlabelled identical screws, ambiguous hole orientation, cluttered diagrams, no room to stop and recover mid-task

**confirmed by**

a literature review across 5 cognitive profiles (ADHD, ASD, AuDHD, Dyslexia, Dyspraxia/DCD) mapped directly onto assembly-specific failure points, plus independent user complaints sourced from IKEA manual criticism threads

**and the wider case for solving it**

over 85% of trials on gamified learning show positive results for neurodivergent learners - so the gamification is the method, not decoration

## < PHASE 02: DEFINING THE STRATEGY>

### i/ non-diagnostic personalization

MODU never asks a user to name a condition. A 5-question, non-clinical onboarding quiz — "how do you feel opening a box of parts?", "what keeps you focused while gaming?", etc. — reads behaviour, not labels, and routes each answer to one of four support modes.

### ii/ 4 modes

** claude, for this section, re-create how modes appear in https://modugamified.vercel.app/ , but stylistically adjust to my websites appearance. for companion's images use placeholders*

### iii/ gamification & rewards

**no punishment for failure:** a wrong piece gets a gentle hint & never a progress or currency penalty

**no time pressure:** no countdowns, no speed scoring. XP and coins reward completion, not speed

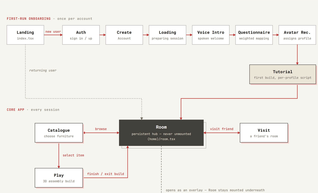
**multimodal confirmation:** every mistake and every success is signalled through at least two channels at once (visual + haptic, or audio + visual)

### iv/ the room as a homescreen

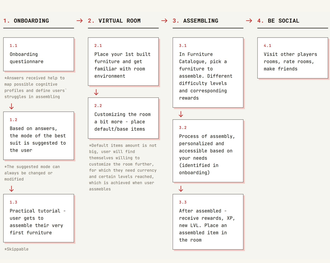
assembly may be an overwhelming task & the room is the reason to come back. Every finished build drags into a space the user furnishes, decorates and shows to friends. the app's front door is a payoff screen (room), not a demanding one (catalogue of furniture to assemble)

## < PHASE 03: DESIGNING>

### i/ information architecture



### ii/ user interaction flow



### iii/ wireframing UI

** claude, for this section, stylistically adjust the inserted above image to my websites appearance.*
